

# Grant Writing Boot Camp Cross-Sectional and Cohort Studies

Feng Liu-Smith, Ph.D Slides modified from Simonne Nouer, MD, PhD

# General Idea: know your goals and weakness of studies

Source: Hulley, Stephen B.. Designing Clinical Research. LWW. Kindle Edition

# Study Design I – Cross Sectional Studies

# **Outline**

- Overview of Epidemiological Study Designs
- Descriptive Studies
- Cross-Sectional
  - Design; Analytical approach; Strengths; Weakness
  - Random error, Systematic error, and Confounding
- Observational Studies
  - Cohort Study
    - Design; Analytical
  - Case-Control Study (Dr. Zhao)

# Two Types of Epidemiology

**Descriptive** 

Describe disease patterns

- 1. To monitor public's health
- 2. To evaluate success of intervention programs
- 3. To generate hypotheses about causes of disease

Identify and count cases of disease in populations and conduct simple studies

- Case Report
- Case Series
- Cross-Sectional Study
- Ecologic Study

Analytic/ Scientific

Search for disease causes and preventions

- 1. To evaluate hypothesis about causes of disease
- 2. To evaluate success of intervention programs

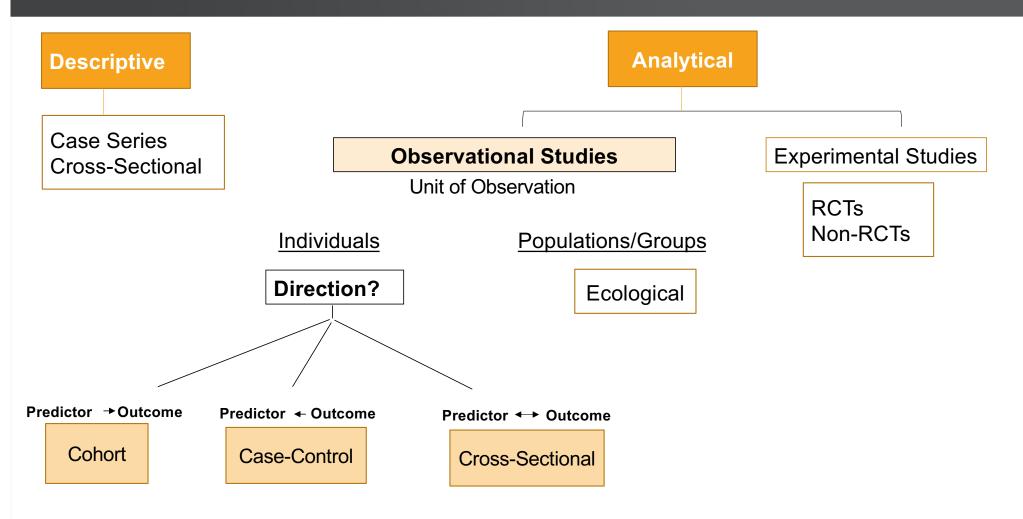

Compare groups & systematically determine: is there an association?

- Clinical Trial
- Experimental Study
- Case-Control Study
- Cohort Study

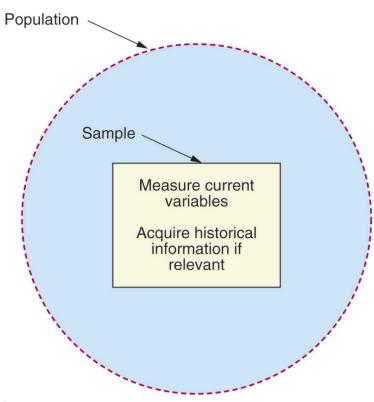

# Epidemiological Study Designs

# CROSS-SECTIONAL STUDY

#### THE PRESENT

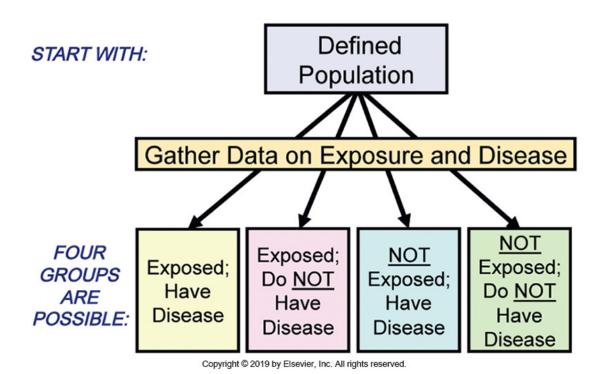

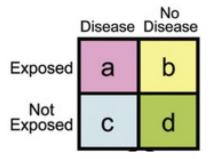

- FIGURE 7.1 In a cross-sectional study, the steps are to:
- Define selection criteria and recruit a sample from the population.
- Measure current values of predictor and outcome variables, often supplemented by historical information.

Source: Hulley et. All,. Designing Clinical Research. LWW. Kindle Edition.

# **Cross-Sectional Studies**

Source: Celentano & Szklo. Gordis Epidemiology. Elsevier Health Sciences.

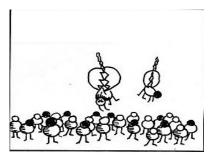

#### **Cross-Sectional Studies**

# Sample Size – needs to be calculated

# Sampling Methods

- Random sampling: purest form of probability sampling. Each member of the population has an equal chance of being selected.
- Systematic sampling: use of pre-established sequences to select from a source of participants (e.g. medical records)
- Stratified sampling: sample based on certain demographic characteristics, (systematic or random sampling)
- Convenience sampling: the sample is selected because they are convenient (college students, patients, person on the street)

# **Cross-Sectional Studies – When to use**

- Goal is to describe variables and their distribution pattern
  - Example: National Health and Nutrition Examination Survey (NHANES study)
    - Sample designed to represent the US population -- interviewed and examined
    - Each cross-sectional study -- major source of information on health and habits of the US population (e.g., prevalence of smoking in various demographic groups)
- Can be used to examine associations
  - Which variables to label as predictors and outcome depends on the investigator hypothesis
  - Temporal relationship usually cannot be established

#### **Cross Sectional**

# **Cross-Sectional Studies**

# **Analytical Approach**

	Outco	ome	Total
Exposure	Present	Absent	
Yes	a	b	a + b
No	c	d	c + d
Total	a + c	b + d	a+b+c+d

Prevalence  $_{total}$  = ((a+c) / (a+b+c+d)) x 10<sup>n</sup>

Prevalence  $_{exposed} = (a / (a+b)) \times 10^{n}$ 

Prevalence  $_{\text{non-exposed}} = (c / (c+d)) \times 10^{n}$ 

Measure of association

Prevalence Ratio = P<sub>exposed</sub> /P <sub>non-exposed</sub>

#### Example of a cross-sectional study

# **Cross-Sectional Studies: Example 7.1**

# **Analytical Approach**

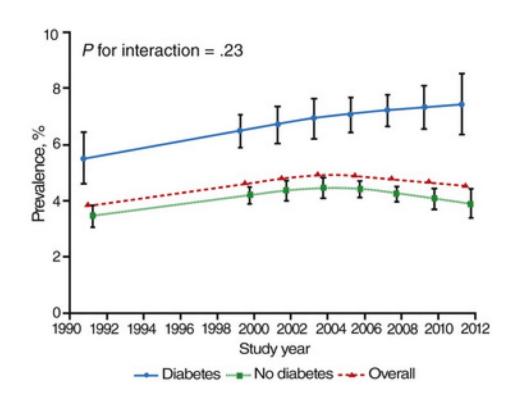

Sargent et al. (2) sought to determine whether exposure to movies in which the actors smoke is associated with smoking initiation. The steps in performing the study were to:

- I. Define selection criteria and recruit the population sample. The investigators did a random-digit-dial survey of 6,522 U.S. children aged 10 to 14 years.
- 2. Measure the predictor and outcome variables. They quantified smoking in 532 popular movies and for each subject asked which of a randomly selected subset of 50 movies they had seen (predictor variable). Subjects were also asked about a variety of covariates such as age, race, gender, parent smoking and education, sensation-seeking (e.g., "I like to do dangerous things"), and self-esteem (e.g., "I wish I were someone else"). The outcome variable was whether the child had ever tried smoking a cigarette.
- 3. Results and conclusion: 1) Overall, 10% of the population had tried smoking. Quartile (Q) of movie smoking exposure was significantly associated with the prevalence of smoking initiation; 2) This association did not differ significantly by race/ethnicity or census region. 3) After controlling for sociodemographics, friend/sibling/parent smoking, school performance, personality characteristics, and parenting style, the adjusted odds ratio for having tried smoking were 1.7 (95% confidence interval [CI]: 1.1, 2.7) for Q2, 1.8 (95% CI: 1.2, 2.9) for Q3, and 2.6 (95% CI: 1.7, 4.1) for Q4 compared with adolescents in Q1. 4) The covariate-adjusted attributable fraction was 0.38 (95% CI: 0.20, 0.56), suggesting that exposure to movie smoking is the primary independent risk factor for smoking initiation in US adolescents in this age group.

# Serial Survey: a special type of cross-sectional study

# Serial Surveys A cross-sectional following time

Adjusted prevalence of chronic kidney disease in US adults – NHANES – 1988-1994 thorough 2011-2012 .

Source: Murphy et All., Ann Intern Med. 2016;165:473–481. in: Celentano & Szklo. Gordis Epidemiology. Elsevier Health Sciences. Kindle Edition.

# **Cross-Sectional Studies – Random and Systematic Error**

Random error – by chance – may affect precision in both outcome and exposure measures (frequencies or relationship) – solution: increase the sample size

Systematic error (bias) -- can happen in design, conduct, analysis or reporting of a study

#### Selection bias:

Sampling Bias – Not using representative sample of the source population Incidence-Prevalence Bias – Inclusion of prevalent cases in a study (overrepresentation of those who have lived the longest)

#### Information bias:

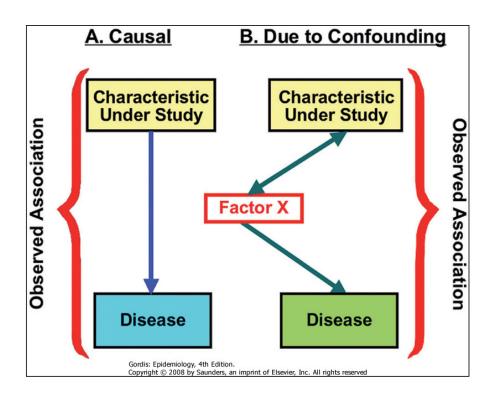

Recall bias – use of self-reporting – differences in accuracy or completeness of recall of past events/experiences

More error details refer to :https://www.ncbi.nlm.nih.gov/pmc/articles/PMC7318122/

# **Cross-Sectional Studies - Confounding**

A distortion in the association between an exposure and disease brought about by extraneous factors (confounders)

# **Cross-Sectional Studies**

# **Strengths**

- No waiting for the outcome to occur
  - Fast; Inexpensive; No loss of follow-up
- Can be a first step in a cohort or a clinical trial

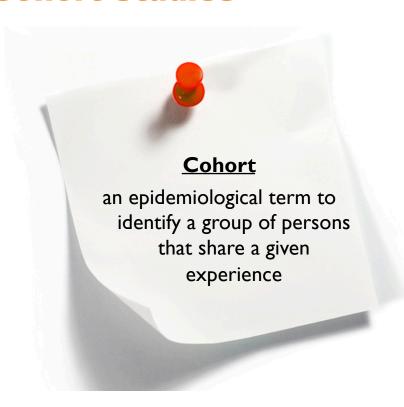

#### Weakness

- Impractical for studies of rare diseases (if collecting data from the general population)
- Not suited for diseases of short-duration
- Difficult to establish causal relationship

# Observational Studies – Cohort Study

# **Cohort Studies**

#### **EXAMPLES**:

**Students** 

**Patients** 

**Employees** 

Migrants

Pregnant women

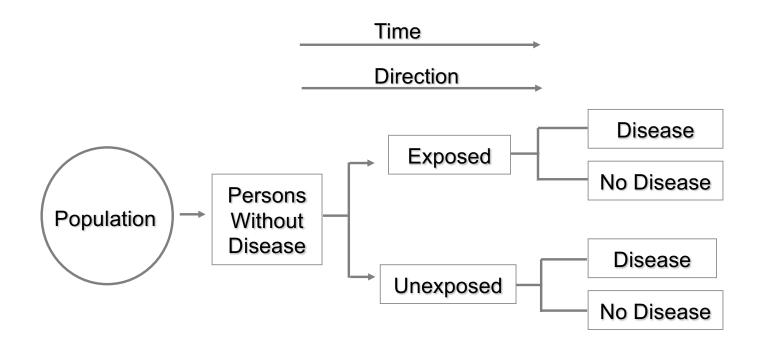

Infants

...etc.

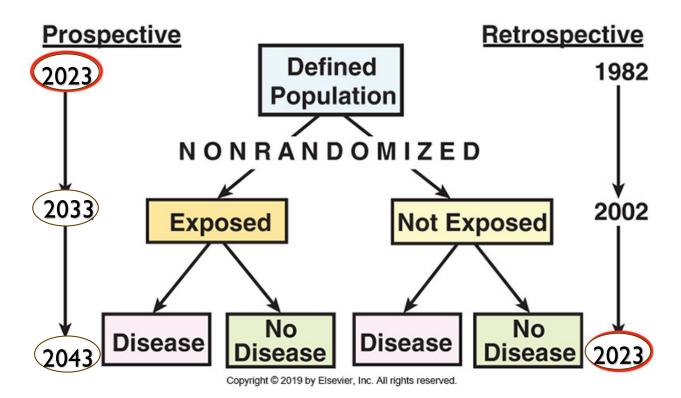

# **Cohort Studies**

# **Types of Cohort Studies**

Source: Celentano & Szklo. Gordis Epidemiology. Elsevier Health Sciences.

# **Prospective Cohort Study**

# The Present The Future Follow-up

Population Sample Measure Predictors Outcome(s) as they occur

Lost to follow-up

# **Prospective Cohort Studies**

# **Strengths**

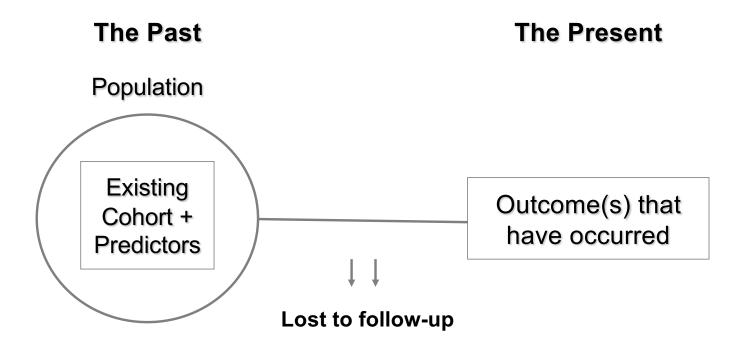

- Allows calculation of incidence, hence estimation of risk
- Temporal relationship between predictors and outcome can be established
- Less possibilities of introducing bias if good criteria and procedures for conducting the study are established in advance
- Information can be obtained on participants whose exposure to risk factors have changed

#### **Weakness**

- Potential for influences of confounding variables
- High cost and long duration
- Inefficient for rare outcomes

# **Retrospective Cohort Study**

# **Retrospective Cohort Studies**

# **Strengths**

- Same as Prospective Cohort
- And...
  - Less costly
  - Less time consuming

#### **Weakness**

 Investigator has limited control over sampling, follow-up of population, quality of baseline measurements

# **Cohort Studies - Analytical Approach**

Exposure or	Developed disease		Total
characteristic	Yes	No	
Present (exposed)	a	b	a + b
Absent (not exposed)	С	d	c + d

Incidence  $_{total}$  = ((a+c) / (a+b+c+d)) x 10<sup>n</sup>

Incidence  $_{exposed}$  = (a / (a+b)) x 10<sup>n</sup>

Incidence  $_{non-exposed} = (c / (c+d)) \times 10^{n}$ 

Measure of association

Relative Risk= I exposed /I non-exposed

When denominator is total time of follow-up for each participant – Rate Ratio

Cox Proportional Hazards --Hazard Ratio

# **Cohort Studies – Issues Reviewers Evaluate and Why**

- Is there a well-characterized cohort defined at the beginning of follow-up?
- Will the sample size be large enough?
- Are cohort members readily available to follow-up?
- Do the measures of predictors/outcomes have good reliability and validity?

Selection bias (inclusion and exclusion criteria)

Random error (a must-have component)

Selection bias (your proposal's feasibility)

Random error & bias (quality of your study)

# **Cohort Studies – Issues Reviewers Evaluate and Why**

- Does the protocol include standardized assessment criteria? (e.g., blinding)
- Have potential confounders and effect modifiers been included?
- What steps will be taken to maximize retention?
- How will the longitudinal data be analyzed appropriately?

Random error & bias (quality of your study)

Confounding (ensuring correct conclusion)

Selection bias from loss to follow-up (feasibility)

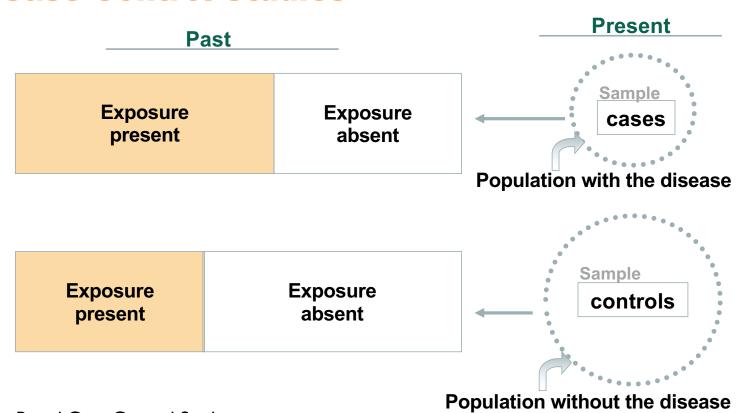

Statistical inference bias (quality of study)

# **Case-Control Study**

Qi Zhao, MD, PhD Associate Professor of Epidemiology Department of Preventive Medicine 10.27.2023

Case-Based Case-Control Study

#### **Selection of Cases**

The source of cases depends on the disease of interest

Hypertension, stroke ---- hospital, clinics
HIV infected individuals ---- STD clinics, community
Cancer ---- Cancer registration

Incident (new case/newly diagnosed) or Prevalent (old case/previously diagnosed) Cases?

#### **Selection of Controls**

- One of the major challenges in a case-control studies
- Controls should be similar to the cases in all respects other than having the disease (event) in question
- Controls should be representative of all persons without the disease in the population from which the cases are selected

# **Multiple Controls**

- Controls from the same source -- two or three controls for each case are used to increase the statistical power of the study
- Controls from different sources e.g., hospital controls and neighbourhood controls.

# **Case-Control Studies – Analytical Approach**

Exposure or	Disease/Event		
characteristic	Cases	Controls	
Present (exposed)	a	b	
Absent (not exposed)	С	d	

Odds Ratio = 
$$(a/b) / (c/d)$$
  
=  $(a*d) / (b*c)$ 

**Logistic Regression** -- Multivariable approach

# **Case-Control Studies – Strengths**

- Efficient for rare outcomes
- Require fewer participants than cohort studies, which means that more expensive and rigorous tests can be used
- There is no problem with losses to follow-up

#### **Case-Control Studies – Weakness**

- Cannot estimate the incidence or prevalence of the diseases
- Information on the exposure or risk factor is obtained <u>after</u> the occurrence of disease, so there is not a clear way to estimate the time between exposure and start of disease
- Only one outcome can be studied
- Susceptibility to bias

# **Case-Control Studies – Weakness**

- Bias sources
  - Selection bias
    - > Control selection
  - Information bias
    - ➤ Recall bias: e.g., patients with disease may overreport a certain exposure
    - ➤ Interviewer bias: e.g., observer may tend to ask cases and controls differently about their exposure

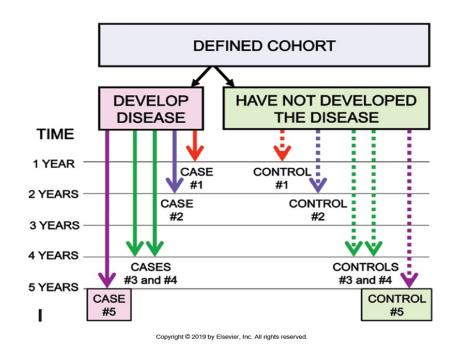

# Confounding

- Matching
  - To increase the comparability of cases and controls by controlling a confounding variable in the study design: controls are matched to cases based on having the same value of the confounder (e.g. age)
  - More than one control may be matched to each case

# **Nested Case-Control Studies**

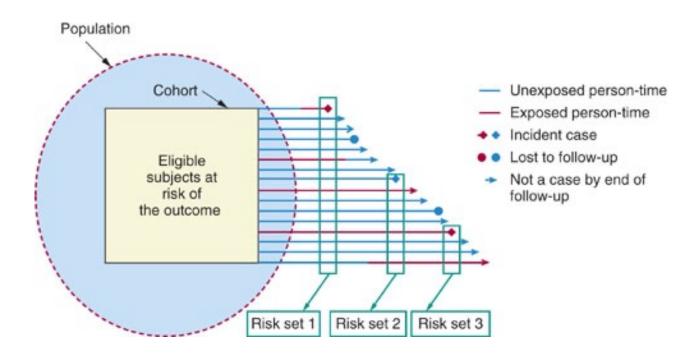

**Nested Case-Control Study** 

Source: Celentano & Szklo. Gordis Epidemiology. Elsevier Health Sciences.

# **Cohort-based Case-Control Studies**

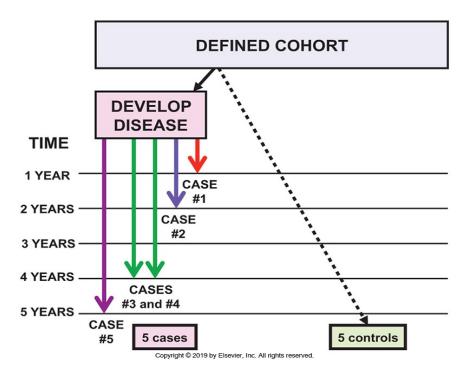

# **Incidence-Density Nested Case-Control Study**

Source: Hulley SB, et al. Designing clinical research. 4th edition.

# **Cohort-based Case-Control Studies**

**Nested Case-Cohort Study** 

Source: Celentano & Szklo. Gordis Epidemiology. Elsevier Health Sciences.

#### **Nested Case-Control Studies**

# Strengths

- Useful for costly measurements on specimens that have been archived at the beginning of the study
- Avoids the potential biases of conventional case—control studies that cannot make measurements on fatal cases and that draw cases and controls from different populations
- Retains the advantages of cohort studies -- collect predictor variables before the outcomes have happened

# Weakness

Same as other observational studies including potential for confounding

# **Considerations in Grant Application**

#### **Bias**

- 1) Study design: e.g., nested case-control study; case or control selection; inclusion and exclusion criteria; multiple control groups
- 2) Data collection: e.g., staff training, blinded to case and control status; additional data collection for evaluating potential bias
- 3) Data analysis plan: e.g., analyze additional data

#### Confounding

- 1) Study design (study population): e.g., matched study design
- 2) Data collection: e.g., collect potential confounding factors
- 3) Data analysis plan: e.g., stratification analysis; multivariable modeling

# **Questions?**
